A Synthetic Pilot Study of StudyFlow: An Example of Internal Reporting Inconsistency

HIGH-RISK TEST CASE — synthetic, deliberately inconsistent
Fictional content constructed for software testing only. Do not cite as research.

Abstract

Background: This fictional example evaluates StudyFlow, a digital coaching program, in 120 adult volunteers. The abstract reports a 30% improvement in task-completion scores. Methods: Participants were assigned to StudyFlow or usual practice for four weeks. Results: The primary outcome shows mean change of 2.1 points in StudyFlow and 2.0 points in comparison; between-group difference 0.1 points (95% CI -0.8 to 1.0; p=0.81). Conclusion: StudyFlow produces a substantial and statistically significant improvement.

1. Introduction

Document-level claim checking compares summary statements with methods, numerical results, discussion, and limitations. This synthetic manuscript tests whether a screening system identifies alignment or possible overstatement across sections.

2. Methods

120 volunteers were assigned, 60 per group. The prespecified primary endpoint was change in a 20-point task-completion score from baseline to week four. No external validation cohort was included.

3. Results

At week four, mean change was 2.1 points (SD 3.4) in StudyFlow and 2.0 points (SD 3.2) in usual practice. The between-group difference was 0.1 points (95% CI -0.8 to 1.0; p=0.81). Data were available for 108 of 120 participants. No prespecified analysis supporting a 30% relative improvement is reported.

4. Discussion

The numerical results show little evidence of a between-group difference. Nevertheless, the abstract and conclusion describe a substantial, statistically significant benefit. This mismatch is intentionally included to test discrepancy detection.

5. Limitations

This is synthetic demonstration material. The sample is small, follow-up is short, and missing outcome data may affect estimates. The confidence interval includes both modest benefit and modest harm. No confirmatory trial is available.

6. Conclusion

StudyFlow produces a substantial and statistically significant improvement in task completion. This conclusion is intentionally overstated relative to the results.
